

Python

Variables full_name = "Jane Hacker" pi = 3.14# lists ("Arrays" in JS) names = ["John", "Paul", "G"] # dicts (similar to "Objects") translation = { "ola": "Hello", "oi": "hi", # For loops for name in names: print("name:", name) # While loops while x < 3: print("X:", x) x += 1# If-statements if full_name == "Jane": print("Hi, Jane!") elif full_name == "Alice": print("Hey Alice") print("Don't know you") # List comprehension long_names = [name.upper() for name in names if len(name) > 3] # Functions def greeter(name): print("Hi", name) greeter("Bob") # Lambda function dst = lambda x, y: x*x + y*y# Conjunctions if age < 18 and drink == "beer": print("Too young kiddo") if age > 18 or drink == "soda": print("Great choice") # Class syntax class User(BaseUser): def __init__(self, name): self.name = name self.logged_in = False def log_in(self): self.logged_in = True user = User("jqhacker")

JAVASCRIPT

```
// Variables
let fullName = "Jane Hacker";
const pi = 3.14;
// Arrays ("lists" in Py)
let names = ["John", "Paul", "G"];
// Objects (similar to "dicts")
let translation = {
    ola: "Hello",
    oi: "Hi",
};
// For loop
for (let name of names) {
    console.log("name:", name);
// While loops
let x = 0;
while (x < 3) {
    console.log("X:", x);
    x++:
// If-statements
if (fullName === "Jane")
    console.log("Hi, Jane!");
} else if (fullName === "Alice") {
    console.log("Hey Alice");
} else {
// Array processing (map & filter)
let longNames = names
    .filter(n => n.length > 3)
    .map(n => n.toUpperCase());
// Functions
function greeter(name) {
    console.log("Hi", name);
greeter("Bob");
// Arrow function expression
const dst = (x, y) \Rightarrow x*x + y*y;
// Conjunctions
if (age < 18 && drink === "beer") {asynchronous Instead
    console.log("Too young kiddo");
if (age > 18 || drink === "soda") {
    console.log("Great choice");
// Class syntax
class User extends BaseUser {
    constructor(name)
        this.name = name;
        this.loggedIn = false;
    logIn() {
        this.loggedIn = true;
let user = new User("jqhacker");
```

MODERN JS FOR PYTHONISTAS

Collection operations

```
// Destructuring object
                               let {ola, oi} = translation;
                                // ...and the reverse
                               const age = 3;
                               let info = {fullName, age};
                                // Combine obj, arrays with splat
                               const addedTranslations = {
                                    ...translation,
                                   gato: "cat",
                               const extra = [...names, "Mary"];
                               LEGACY SYNTAX
                               // Loop through properties
                               for (var i in arr) {}
                                // C-style: Loop through numbers
                               for (var i = 0; i < 100; i++) {}
var a = 3; // function-scoped</pre>
                               a = 3; // globally scoped
                               Async & Callbacks
(err, data) => {
                                   if (err) throw err;
                                    console.log(data);
                               });
                                // Promise (common in browser)
                               fetch("http://site.com/api.json")
                                .then(response => response.json())
                                .then(data => {
                                    console.log("Resp:", data);
                               })
                                .catch(err => {
                                    console.log("error", err);
                               });
                                                     of pausing
                                     ("blocking") for a slow operation,
                                    the asynchronous approach is to
                                    put-off starting the slow operation,
                                    then call a function ("callback")
                                    at a later time to signal it's done
                               callback A function passed as an argu-
                                    ment to be called later when an
                                    event is triggered
                               promise Another popular way to do
                                    callbacks, with a .then syntax
                                Variable Declaration
```

let Declare a variable (block scoped) const Like let, cannot be reassigned.
